Lab Title:	Java Database Connectivity
Drs:	Dr/Khaled Nagi
TA:	Eng/Abdelrahman Hany

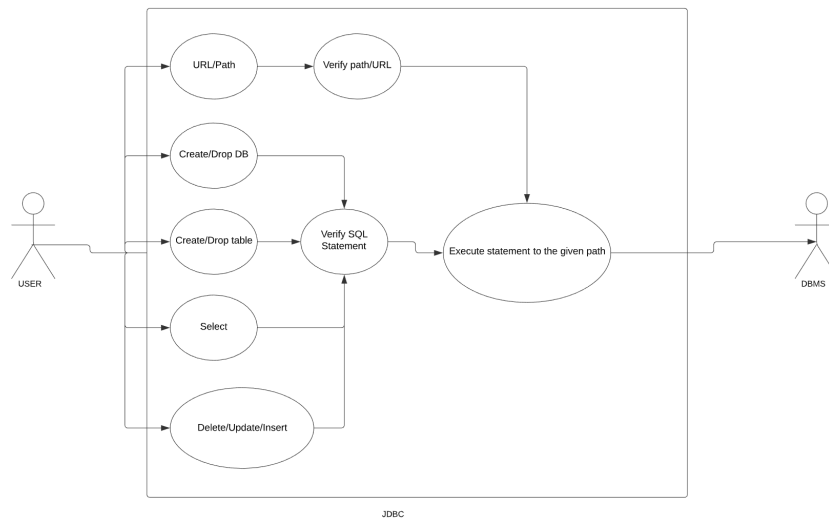

Computer and Systems Engineering Department

1 Introduction

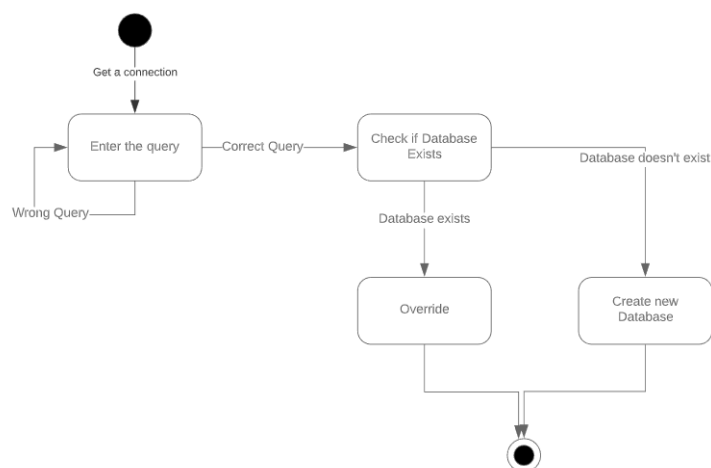

Java Database Connectivity (JDBC) provides Java developers with a standard API that is used to access databases, regardless of the driver and database product. JDBC presents a uniform interface to databases - change vendors and your applications only need to change their driver.

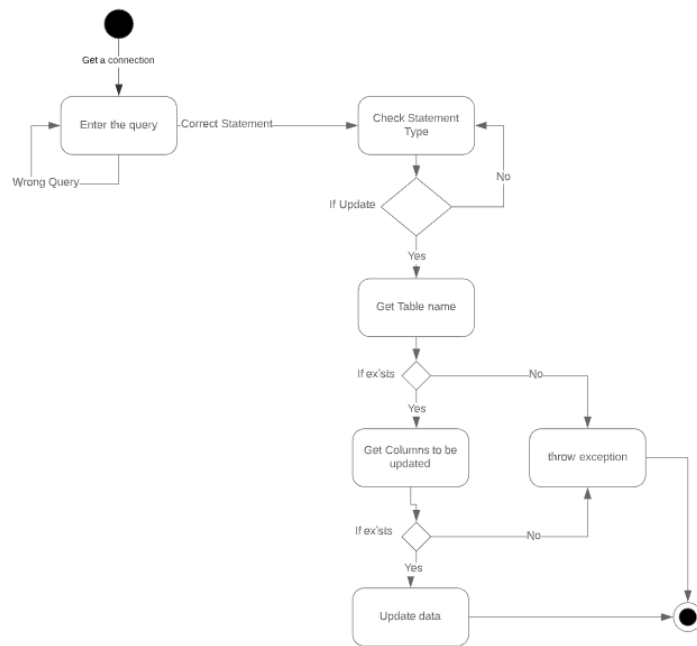

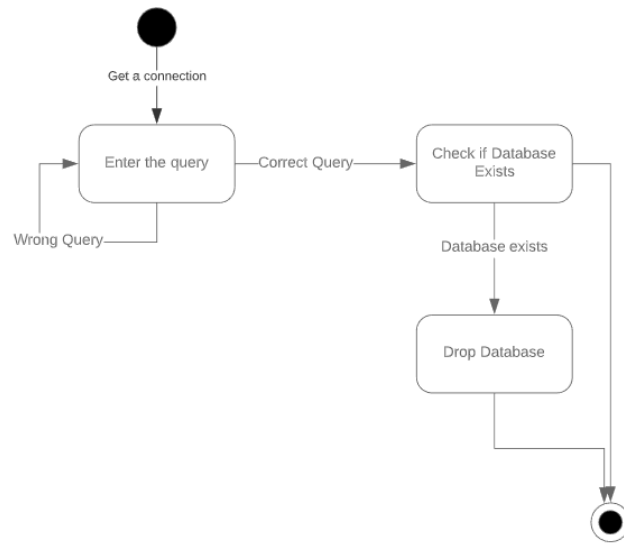

2 UML Diagrams

2.1 Use Case

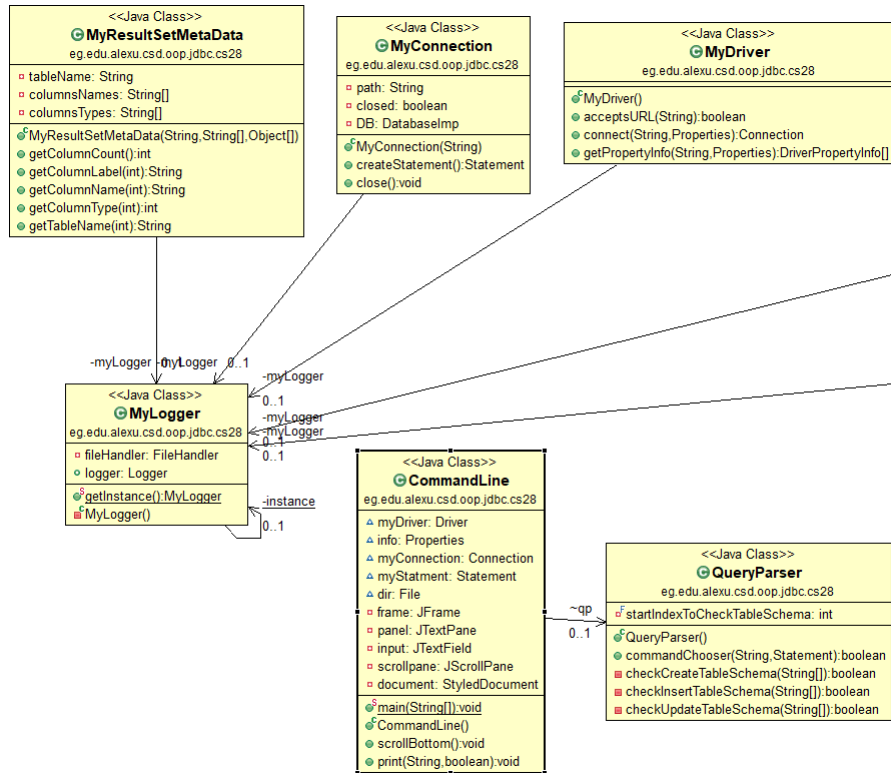

2.2 State Diagrams

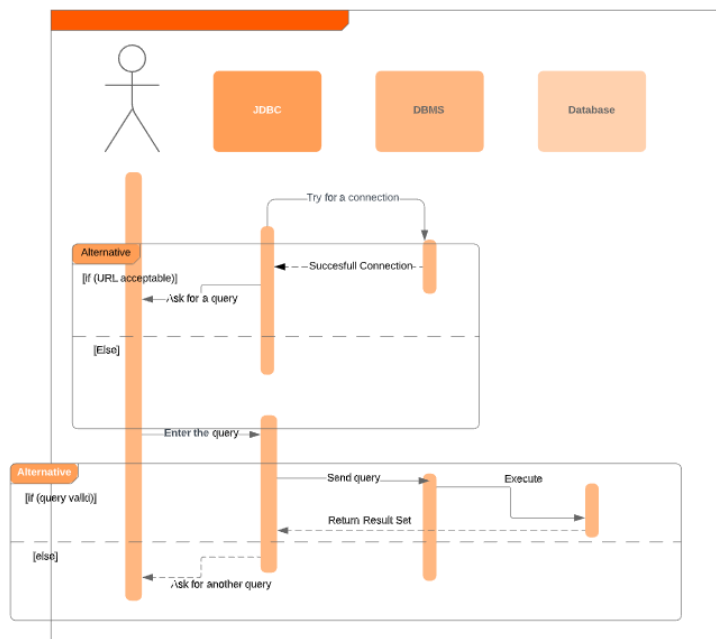

2.3 Detailed Class Diagram

2.4 Sequence Diagram

3 Design

****Design decisions are bold****

Assumptions are italic

3.1 Driver

1. For establishing a connection it needs to check if the URL is acceptable according to the format "jdbc:xmlldb://localhost" and that properties contains valid path.
2. It collects the property info through the key set of Properties.

3.2 Connection

1. Once a successful connection is established it creates an instance of the driver implementation which is sent to the statement for executing queries by create Statement.
2. It contains a Boolean which indicates if the connection is open or closed.

3.3 Taking Queries from User

- SQL queries are sent to class QueryParser which checks the validity of the statement.
- Valid statements are sent to the appropriate method.

3.4 SQL Statements Execution

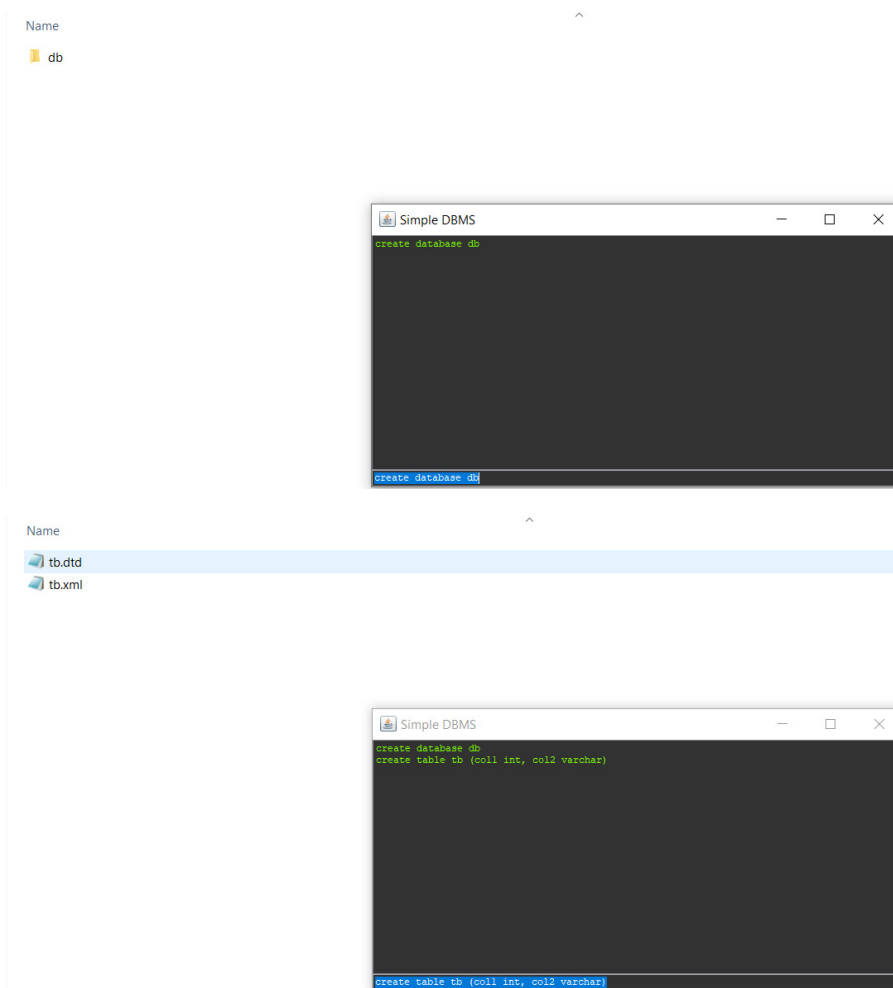

- Execute Structure Queries:
 1. Send the SQL statement to the method responsible for structure queries in the DBMS.
- Execute Select Queries:
 1. Send the SQL statement to the method responsible for select queries in the DBMS.
- Execute Update Queries:
 1. Send the SQL statement to the method responsible for update queries in the DBMS.

3.5 Result Set

- After executing a select query successfully and the return is not null.
- A result set object is created with these information send to the constructor:
 1. A 2D array of objects which contain the table data.
 2. The table name.

3. An array of the columns' names.
- One of the methods of the result set class creates an object of result set meta data and these information are passed to the constructor:
 1. The table name.
 2. An array of the columns' names.
 3. A row from the table itself.

4 Sample Runs

tb.xml - Notepad

File Edit Format View Help

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<!DOCTYPE table SYSTEM "tb.dtd">
<table col1="int" col2="varchar">
  <row>
    <col1>111</col1>
    <col2>asd</col2>
  </row>
  <row>
    <col1>111</col1>
    <col2>daa</col2>
  </row>
</table>
```

Simple DBMS

```
create database db
create table tb (col1 int, col2 varchar)
insert into tb values (5 , asd)
insert into tb values (52 , asdaa)
insert into tb values (542 , daa)
update tb set col1 = 111
delete from tb where col2 = asdaa
```

Delete from tb where col2 = asdaa

Name

This folder is empty.

Simple DBMS

```
create database db
create table tb (col1 int, col2 varchar)
insert into tb values (5 , asd)
insert into tb values (52 , asdaa)
insert into tb values (542 , daa)
update tb set col1 = 111
delete from tb where col2 = asdaa
drop table dbb
drop table tb
drop database dbb
drop database db
```

drop database db

Simple JDBC

Enter your database folder path
connected successfully...
create database db

CommandLine (1) [Java Application] C:\Program Files\Java\jre1.8.0_231\bin\javaw.exe (D

```
